INTRODUCTION

GDP per capita measures the economic output of a nation per person.

The economic output of a nation or region per person is measured by the GDP per capita.

The GDP per capital of some regions of the world over the period of 48 years. The data was gotten from the world bank database. GDP per capita is gross domestic product divided by midyear population. GDP is the sum of gross value added by all resident producers in the economy plus any product taxes and minus any subsidies not included in the value of the products. It is calculated without making deductions for depreciation of fabricated assets or for depletion and degradation of natural resources. Data are in current U.S. dollars.

In this exercise we will be Classifying the GDP per Capita of 2 regions over a period of 49 years into 4 Using K-MEAN clustering algorithms from python sklearn library.

Building a model that fits the data using the scipy.optimize from python and predicting the GDP per capita of 2 regions in 10 years time from 2020 with an error range.

```
In [1]: #import libraries and modules
import pandas as pd
import scipy.optimize as opt
import numpy as np
import sklearn.cluster as cluster

            arrowprops=dict(facecolor='black', shrink=0.05))
plt.annotate("1988 - 2003", xy=(5400, 3800), xytext=(6500, 3000),
            arrowprops=dict(facecolor='black', shrink=0.05))
plt.annotate("2003 - 2009", xy=(8400, 6400), xytext=(9400, 5800),
            arrowprops=dict(facecolor='black', shrink=0.05))
plt.annotate("2009 - 2020", xy=(10600, 8800), xytext=(9400, 7200),
            arrowprops=dict(facecolor='black', shrink=0.05))
plt.title('GDP per capita K-mean clustering')
plt.xlabel('world')
plt.ylabel("Latin America & Caribbean")

#save plot
plt.savefig('world.png')
plt.show()
```

The output can be read and explained better when we use the normal data

```
In [16]: #using the fitting_logistics function to curve fit our data
#and plot the perediction and confidence range
fitting_logistics(df.index, df['World'], 2000, 0.2, 1995)
```

13837.064465931062

Forecasted population

GDP per capita in 10years from 2020 is 13837.064465931062

The error range is from 11680.667556841756 to 16054.064288091327

In [15]: *#using the fitting_logistics function to curve fit our data*
#and plot the perediction and confidence range
`fitting_logistics(df.index, df['Latin America & Caribbean'], 2000, 0.2, 1995)`
 11301.636514758851

Forecasted population

GDP per capita in 10years from 2020 is 11301.636514758851

The error range is from 8419.15606475092 to 14159.188642670593

Conclusion

Performing a k mean clustering on the GDP per capital of world vs Latin America and the Caribbean shows how the GDP has grown every decade. It can be observed that a new decade ushers in a new record high GDP per capita.

The logistics model fits the World GDP per capita better compared to the Latin America and Caribbean region data. This is because of the non-steady trend in the GDP per capita of the Latin America and Caribbean region. However, the confidence range computed is robust enough to Predict the GDP per capita in 10 years' time from 2020.
